

Algorithm Leakage-safe benchmarking protocol

Input: D , subject/session IDs, labels y , target-access mode a

Output: subject scores, 95% CI, and audit metadata

```
1: define stratum = dataset x task x protocol x target-access
2: split subjects into train/validation/test folds
3: for each fold  $f$  do
4:     fit preprocessing on training subjects only
5:     tune model using validation subjects only
6:     evaluate locked model on held-out subjects
7: end for
8: aggregate subject scores; report mean, 95% CI, class balance
9: release code, seeds, fold IDs, exclusions, and target access
```

Audit checks: snatched strata; no outside-fold normalization; no test-subject tuning
